

# Configurable Formal Methods for Extreme Modeling

Uli Fahrenberg Axel Legay

IRISA/Inria Rennes

XM 2014

- Extreme modeling needs **model transformations**
- When applied uncritically, model transformations can lead to **errors**
- Need model transformations which are **correct by design**
  - or **checkable by design**
- But correct in relation to **what semantics ??**

# Toy Example, Merge

merge

Syntactic result

Expected result

How to know which associations to move up?

# Toy Example, Slicing

How to know which associations to “pull down” along generalizations?

# How Not to Do

**Problem:** Model transformations have **no semantic understanding**

**First solution:**

- 1 Give **complete formal semantics** to models
- 2 Define **automatic** and **semantically correct** model operators
- 3 **PROFIT!**

**Yes, but:**

- Complete semantics usually **do not exist**
- or are **too complicated** to be useful
- “Software engineers don’t like formal methods”
- **BUMMER**

**Proposal:** bottom-up instead of top-down!

# Research Proposal: My Approach

Improve existing tools for model transformations by making them **partially semantics aware**

- introduce only **partial** semantics, no more than necessary, **parametrized** by high-level user choices
- iterative, bottom-up approach; immediate, gradual results
- fits well with practice in industry

Application of **formal methods** in model-driven engineering

- but in a gentle, bottom-up way, on a **need-to-know** basis

# Technical Example: First Steps

From our **FASE 2014** paper:

- Def.: A **class diagram** is a tuple  
 $\mathcal{C} = (\text{cla}, \text{asc}, \text{gen}, \text{disj}, \text{ccard}, \text{aends}, \text{acards}) \dots$
- Def.:  $\mathcal{C}_1$  **refines**  $\mathcal{C}_2$  ( $\mathcal{C}_1 \leq \mathcal{C}_2$ ) if
  - $\text{cla}_1 \supseteq \text{cla}_2$ ,  $\text{asc}_1 \supseteq \text{asc}_2$ ,
  - $\text{gen}_1 \supseteq \text{gen}_2$ ,  $\text{disj}_1 \supseteq \text{disj}_2$ ,
  - $\text{ccard}_1(c) \subseteq \text{ccard}_2(c)$  for all  $c \in \text{cla}_2$ ,
  - $\text{aends}_1(a) = \text{aends}_2(a)$  for all  $a \in \text{asc}_2$ , and
  - $\text{acards}_1(a)(e) \subseteq \text{acards}_2(a)(e)$  for all  $a \in \text{asc}_2$  and all  $e \in \text{dom}(\text{acards}_2(a))$ .

## Technical Example: First Steps, contd.

(SLE 2013, contd.)

- With  $\leq$ , **semilattice** structure on class diagrams
- Greatest lower bound: **merge**, “ $\odot$ ”
- Partial inverse to merge: **diff**, “ $\setminus$ ”
- (Merge and diff have concrete syntactic definitions)
- Algebra similar to **Girard quantale**
  
- Using *one choice* of a globally fixed semantics,  
 $\mathcal{M} \models \mathcal{C}_1$  and  $\mathcal{C}_1 \leq \mathcal{C}_2$  imply  $\mathcal{M} \models \mathcal{C}_2$ . (1)
  
- Together with the algebraic properties above, (1) directly implies good semantic properties of merge and diff.
- Easy path to parametrization: **What semantic properties are needed to prove (1)?**

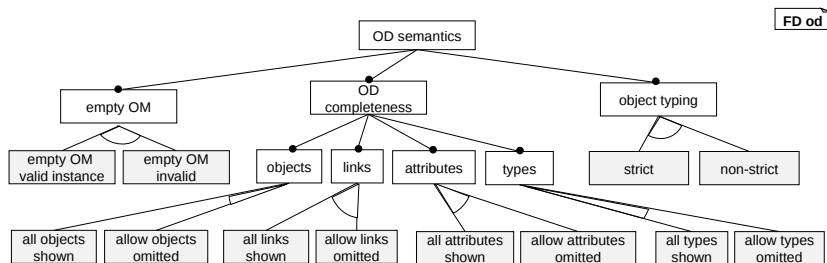

# Variability in Semantics

How to introduce **parametrized semantics**:

- question of **variability**!
- Rumpe's idea: use **feature diagram**:

Semantically Configurable Consistency Analysis for CDs and ODs
