$$\llbracket \phi \rrbracket(s) = 3.14$$
$$d(s, t) = 42$$

Quantitative Quantitative Quantitative Analysis

Quantitative Models

Quantitative Logics

$$\Pr_{\leq .1}(\diamond error)$$

Quantitative Verification

$$\llbracket \phi \rrbracket(s) = 3.14$$

$$d(s, t) = 42$$

Boolean world

Trace equivalence \equiv

Bisimilarity \sim

$s \sim t$ implies $s \equiv t$

$s \models \phi$ or $s \not\models \phi$

$s \sim t$ iff $\forall \phi : s \models \phi \Leftrightarrow t \models \phi$

“Quantification”

Linear distances d_L

Branching distances d_B

$d_L(s, t) \leq d_B(s, t)$

$\llbracket \phi \rrbracket(s)$ is a quantity

$d_B(s, t) = \sup_{\phi} d(\llbracket \phi \rrbracket(s), \llbracket \phi \rrbracket(t))$

Quantitative Quantitative Quantitative Analysis

Problem: For processes with quantities, lots of different ways to measure distance

- point-wise
- accumulating
- limit-average
- discounted
- maximum-lead
- Cantor
- discrete
- etc.

$$D(\sigma, \tau) = \sup_i |\sigma_i - \tau_i|$$

$$D(\sigma, \tau) = \sum_i |\sigma_i - \tau_i|$$

$$D(\sigma, \tau) = \limsup_N \frac{1}{N} \sum_{i=0}^N |\sigma_i - \tau_i|$$

$$D(\sigma, \tau) = \sum_i \lambda^i |\sigma_i - \tau_i|$$

$$D(\sigma, \tau) = \sup_N \left| \sum_{i=0}^N \sigma_i - \sum_{i=0}^N \tau_i \right|$$

$$D(\sigma, \tau) = 1 / (1 + \inf \{j \mid \sigma_j \neq \tau_j\})$$

$$D(\sigma, \tau) = 0 \text{ if } \sigma = \tau; \infty \text{ otherwise}$$

Three ideas:

- For an application, it is easiest to define distance between **system traces** (executions)
- Use **games** to convert these *linear* distances to *branching* distances
- (this paper) Use other games to **compute** branching distances

The Simulation Game

Spoiler

Duplicator

Spoiler wins

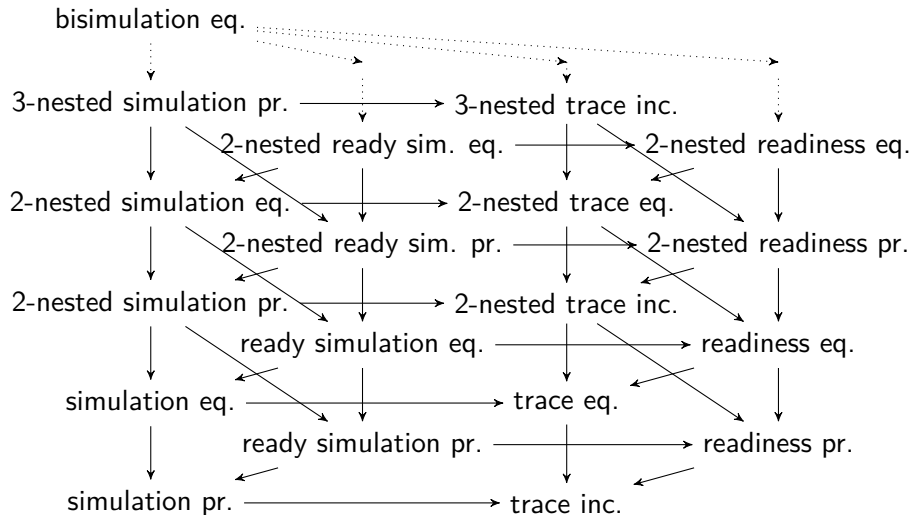

The Simulation Game

1. Player 1 (“**Spoiler**”) chooses edge from s (leading to s')
 2. Player 2 (“**Duplicator**”) chooses matching edge from t (leading to t')
 3. Game continues from configuration s', t'
- ω . If Player 2 can always answer: YES, t simulates s .
Otherwise: NO

- 5 Conclusion

The Simulation Game, Revisited

1. Player 1 chooses edge from s (leading to s')
 2. Player 2 chooses matching edge from t (leading to t')
 3. Game continues from configuration s', t'
- ω . If Player 2 can always answer: YES, t simulates s .
Otherwise: NO

Or, as an Ehrenfeucht-Fraïssé game:

1. Player 1 chooses edge from s (leading to s')
 2. Player 2 chooses edge from t (leading to t')
 3. Game continues from new configuration s', t'
- ω . At the end (maybe after infinitely many rounds!),
compare the chosen traces:
If the trace chosen by t matches the one chosen by s : YES
Otherwise: NO

Quantitative Ehrenfeucht-Fraïssé Games

The quantitative setting:

- Assume we have a way, possibly application-determined, to **measure distances** of (finite or infinite) traces
- a hemimetric $D : (\sigma, \tau) \mapsto D(\sigma, \tau) \in \mathbb{R}_{\geq 0} \cup \{\infty\}$

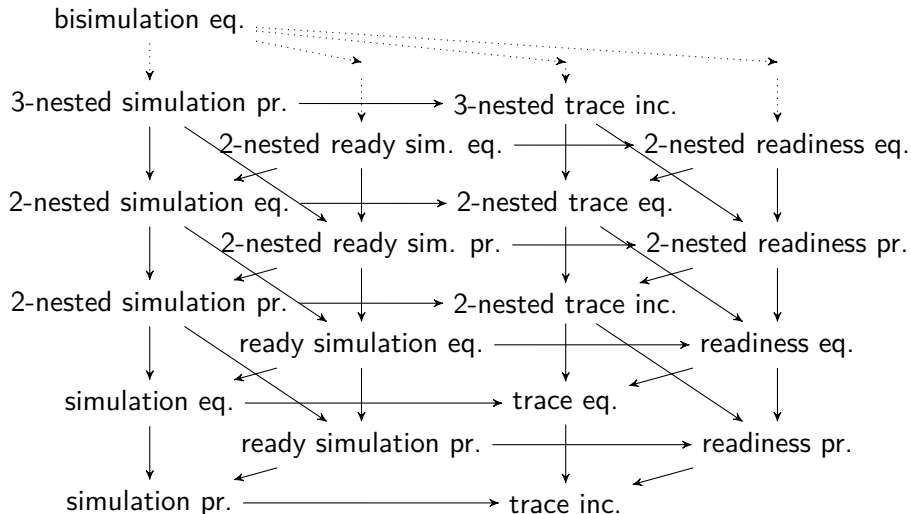

The quantitative Ehrenfeucht-Fraïssé game:

1. Player 1 chooses edge from s (leading to s')
 2. Player 2 chooses edge from t (leading to t')
 3. Game continues from new configuration s', t'
- ω . At the end, compare the chosen traces σ, τ :
The **simulation distance** from s to t is defined to be $D(\sigma, \tau)$
- Player 1 plays to **maximize** $D(\sigma, \tau)$; Player 2 plays to **minimize** $D(\sigma, \tau)$

This can be done for all the games in the LTBT spectrum.

The Quantitative Linear-Time–Branching-Time Spectrum

For any trace distance $D : (\sigma, \tau) \mapsto D(\sigma, \tau) \in \mathbb{R}_{\geq 0} \cup \{\infty\}$:

Transfer Theorem

- Given two equivalences or preorders in the *qualitative* setting for which there is a *counter-example* which separates them, then the two corresponding distances are **topologically inequivalent**
- (under certain mild conditions for the trace distance)
- (The proof uses precisely the same counter-example)

- 5 Conclusion

Path-Building Games

- Have seen how branching distances can be **defined** using a type of “double path-building game”
- But now, how to **compute** them?
- Nothing in the literature about computing values of double path-building games. . .
- On the other hand, people know how to compute values of **(single) path-building games!**
 - ▶ reachability games; discounted games; mean-payoff games, . . .
- So, let’s convert our double path-building games to single path-building games

From Double to Single Path-Building Games

- Let $D : (\sigma, \tau) \mapsto D(\sigma, \tau) \in \mathbb{R}_{\geq 0} \cup \{\infty\}$ be a hemimetric on traces
- Assume that we have functions val_D and f_D such that always,

$$D(\sigma, \tau) = \text{val}_D(0, f_D(\sigma_0, \tau_0), 0, f_D(\sigma_1, \tau_1), 0, \dots)$$

- Let $\mathcal{S} = (S, i, T)$ and $\mathcal{S}' = (S', i', T')$ be LTS
- Construct a game $\mathcal{U} = \mathcal{U}(\mathcal{S}, \mathcal{S}') = (U_1 \cup U_2, u_0, \rightarrow)$ by

$$U_1 = S \times S' \quad U_2 = S \times S' \times \Sigma \quad u_0 = (i, i')$$

$$\rightarrow = \{(s, s') \xrightarrow{0} (t, s', a) \mid (s, a, t) \in T\}$$

$$\cup \{(t, s', a) \xrightarrow{f_D(a, a')} (t, t') \mid (s', a', t') \in T'\}$$

- Path-building game: players alternate to build **path** π
- Player 1 plays to **maximize** $\text{val}_D(\pi)$; Player 2 plays to **minimize** $\text{val}_D(\pi)$

Computing Distances Using Path-Building Games

$\mathcal{U}(\mathcal{S}, \mathcal{S}') = (U_1 \cup U_2, u_0, \rightarrow)$:

$$U_1 = \mathcal{S} \times \mathcal{S}' \quad U_2 = \mathcal{S} \times \mathcal{S}' \times \Sigma \quad u_0 = (i, i')$$

$$\rightarrow = \{(s, s') \xrightarrow{0} (t, s', a) \mid (s, a, t) \in T\}$$

$$\cup \{(t, s', a) \xrightarrow{f_D(a, a')} (t, t') \mid (s', a', t') \in T'\}$$

Theorem

The value of $\mathcal{U}(\mathcal{S}, \mathcal{S}')$ is the *simulation distance* from \mathcal{S} to \mathcal{S}' .

Computing Distances Using Path-Building Games, contd.

$\mathcal{V}(S, S') = (V_1 \cup V_2, v_0, \rightarrow)$:

$$V_1 = S \times S' \quad V_2 = S \times S' \times \Sigma \times \{1, 2\} \quad v_0 = (i, i')$$

$$\begin{aligned} \rightarrow = & \{(s, s') \xrightarrow{0} (t, s', a, 1) \mid (s, a, t) \in T\} \\ & \cup \{(s, s') \xrightarrow{0} (s, t', a', 2) \mid (s', a', t') \in T'\} \\ & \cup \{(t, s', a, 1) \xrightarrow{f_D(a, a')} (t, t') \mid (s', a', t') \in T'\} \\ & \cup \{(s, t', a', 2) \xrightarrow{f_D(a, a')} (t, t') \mid (s, a, t) \in T\} \end{aligned}$$

Theorem

The value of $\mathcal{V}(S, S')$ is the *bisimulation distance* between S and S' .

- Similar constructions for **all** distances in the linear-time–branching-time spectrum

Coda: Computing the Values of Path-Building Games

$\mathcal{U}(\mathcal{S}, \mathcal{S}') = (U_1 \cup U_2, u_0, \rightarrow)$:

$$U_1 = S \times S' \quad U_2 = S \times S' \times \Sigma \quad u_0 = (i, i')$$

$$\begin{aligned} \rightarrow = & \{(s, s') \xrightarrow{0} (t, s', a) \mid (s, a, t) \in T\} \\ & \cup \{(t, s', a) \xrightarrow{f_D(a, a')} (t, t') \mid (s', a', t') \in T'\} \end{aligned}$$

- discrete distance: reachability game
- point-wise distance: weighted reachability game
- discounted distance: discounted game
- limit-average distance: mean-payoff game
- maximum-lead distance: energy game
- Cantor distance: iterated reachability game

Conclusion & Further Work

- A general method to **define** linear and branching system distances using double path-building games
- A general method to **compute** linear and branching system distances using (single) path-building games
- Application to real-time and hybrid systems
- Quantitative specification theories
- Quantitative LTBT with silent moves?
- What about probabilistic systems?

Quantitative EF Games: The Gory Details – 1

- **Configuration** of the game: (π, ρ) : π the Player-1 choices up to now; ρ the Player-2 choices
- **Strategy**: mapping from configurations to next moves
 - ▶ Θ_i : set of Player- i strategies
- **Simulation** strategy: Player-1 moves allowed from **end of π**
- **Bisimulation** strategy: Player-1 moves allowed from **end of π or end of ρ**
 - ▶ (hence π and ρ are generally not paths – “**mingled paths**”)
- Pair of strategies \implies (possibly infinite) sequence of configurations
- Take the limit; unmingle \implies pair of (possibly infinite) traces (σ, τ)
- **Bisimulation distance**: $\sup_{\theta_1 \in \Theta_1} \inf_{\theta_2 \in \Theta_2} D(\sigma, \tau)$
- **Simulation distance**: $\sup_{\theta_1 \in \Theta_1^0} \inf_{\theta_2 \in \Theta_2} D(\sigma, \tau)$ (**restricting Player 1's capabilities**)

Quantitative EF Games: The Gory Details – 2

- **Blind Player-1 strategies:** depend only on the **end** of ρ
 - ▶ (“cannot see Player-2 moves”)
 - ▶ $\tilde{\Theta}_1$: set of blind Player-1 strategies
- **Trace inclusion distance:** $\sup_{\theta_1 \in \tilde{\Theta}_1^0} \inf_{\theta_2 \in \Theta_2} D(\sigma, \tau)$
- For **nesting**: count the number of times Player 1 choses edge from **end of ρ**
 - ▶ Θ_1^k : k choices from end of ρ allowed
- **Nested simulation distance:** $\sup_{\theta_1 \in \Theta_1^1} \inf_{\theta_2 \in \Theta_2} D(\sigma, \tau)$
- **Nested trace inclusion distance:** $\sup_{\theta_1 \in \tilde{\Theta}_1^1} \inf_{\theta_2 \in \Theta_2} D(\sigma, \tau)$
- For **ready**: allow extra “I’ll see you” Player-1 transition from end of ρ
